Climate Modeling

Spring 2015

Lecture 4

- Climate Sensitivity (wrap-up)
- Stochastic Climate Models
- Meridional Energy Transport

April 13

Reading

- Today's lecture: Textbook chapters 4.1 & 4.2; Course Notes chapter 2.3 - 2.4
- For Wednesday: Course Notes chapter 2.5
- For Friday: Huybers & Curry (2012) Anastasiya will lead discussion

Previous Lecture

Climate Sensitivity

Usual definition:

Global mean temperature increase due to a doubling of CO₂: ΔT_{2xC} .

Radiative forcing due to CO₂: $\Delta Q = 5.35 \text{ W/m}^2 \ln(C/C_0)$

For 2xCO₂: $\Delta Q_{2xC} = 3.7 \text{ W/m}^2$

More general:

$$\alpha = \frac{\Delta T}{\Delta Q}$$

global mean temperature change

radiative forcing := change in energy balance at the tropopause with everything else (T, q, ...) constant

Our EBM in equilibrium:

$$(1 - a) S = A + B T_0$$

$$(1 - a) S + \Delta Q = A + B (T_0 + \Delta T)$$

→ $\alpha = \frac{1}{B} = 0.3 \text{ K (W m}^{-2}\text{)}^{-1}$ **Climate Sensitivity**

or $\Delta T_{2\times C} = 1 \text{ K}$

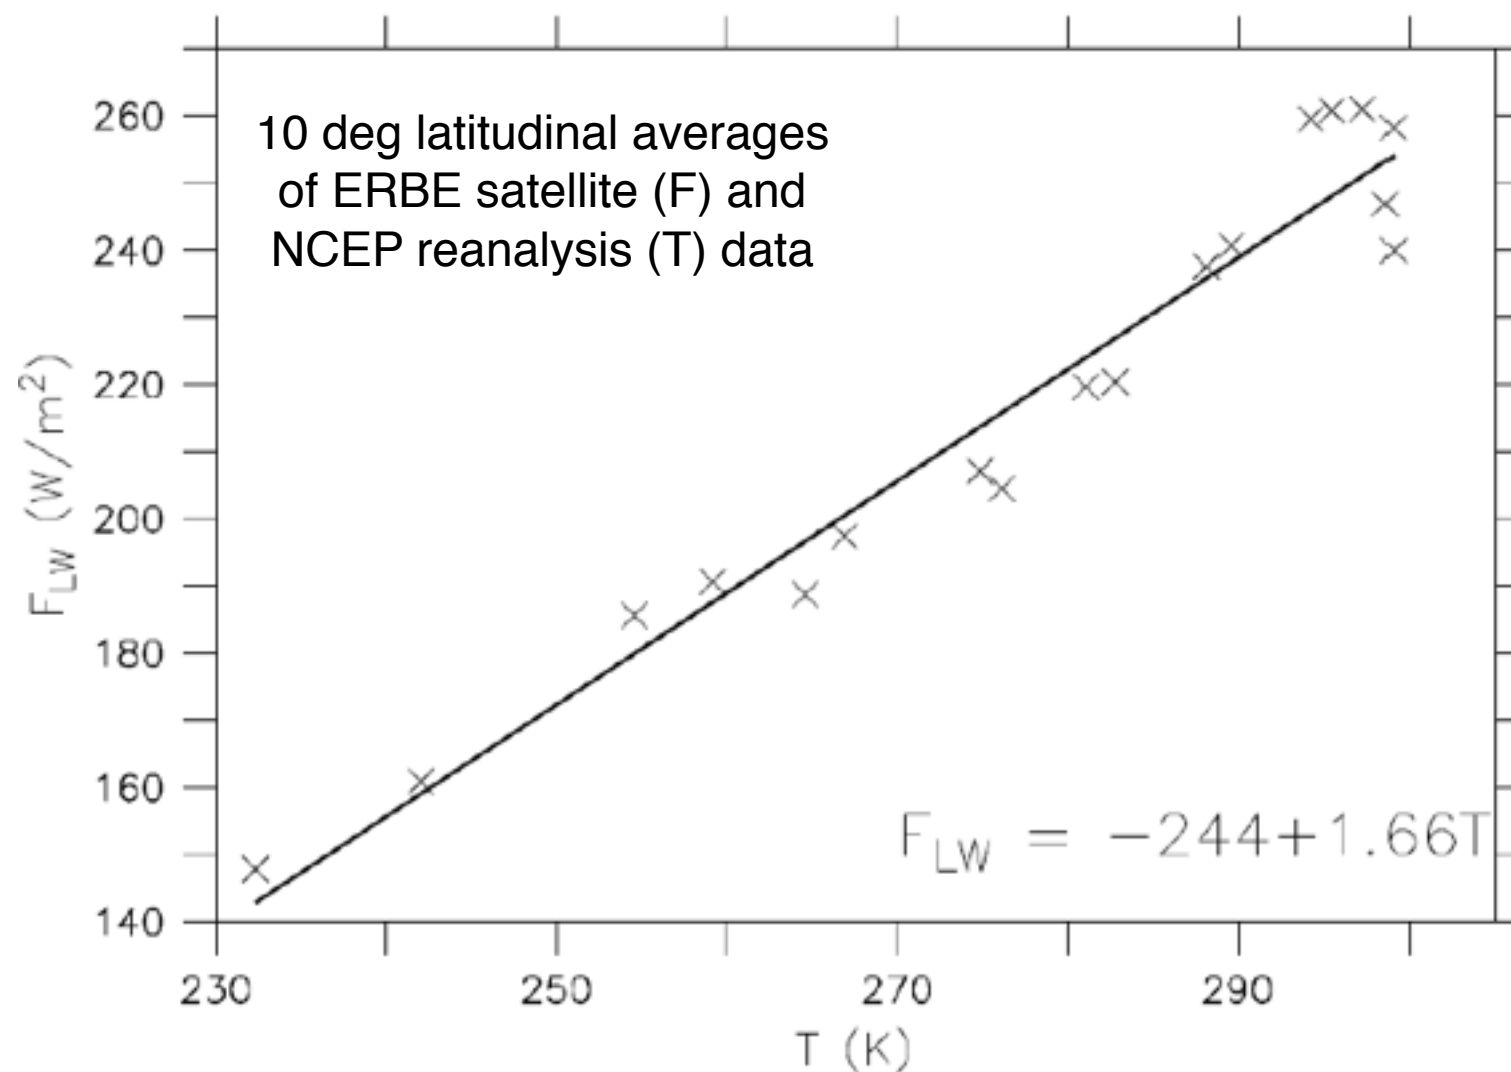

GCMs have $\Delta T_{2\times C} = 2\text{-}4.5 \text{ K}$

What's wrong?

$$B = 4g\sigma T_0^3 = \begin{cases} 3.4 \text{ Wm}^{-2}\text{K}^{-1}, T_0 = 288\text{K} \\ 1.7 \text{ Wm}^{-2}\text{K}^{-1}, T_0 = 227\text{K} \end{cases}$$

surface
tropopause

Determine B empirically from obs:

Implicitly includes feedbacks.

$$\frac{\partial T}{\partial t} = F(T, y_1, y_2, \dots, y_n) \quad F_0 = F(T_0, y_{10}, \dots, y_{n0}) = 0$$

$$\frac{\partial (T_0 + \Delta T)}{\partial t} = F_0 + \frac{\partial F}{\partial T} \bigg|_{T_0, \vec{y}_0} \Delta T + \sum_n \left(\frac{\partial F}{\partial y_n} \frac{\partial y_n}{\partial T} \right) \bigg|_{T_0, \vec{y}_0} \Delta T + \Delta Q = 0$$

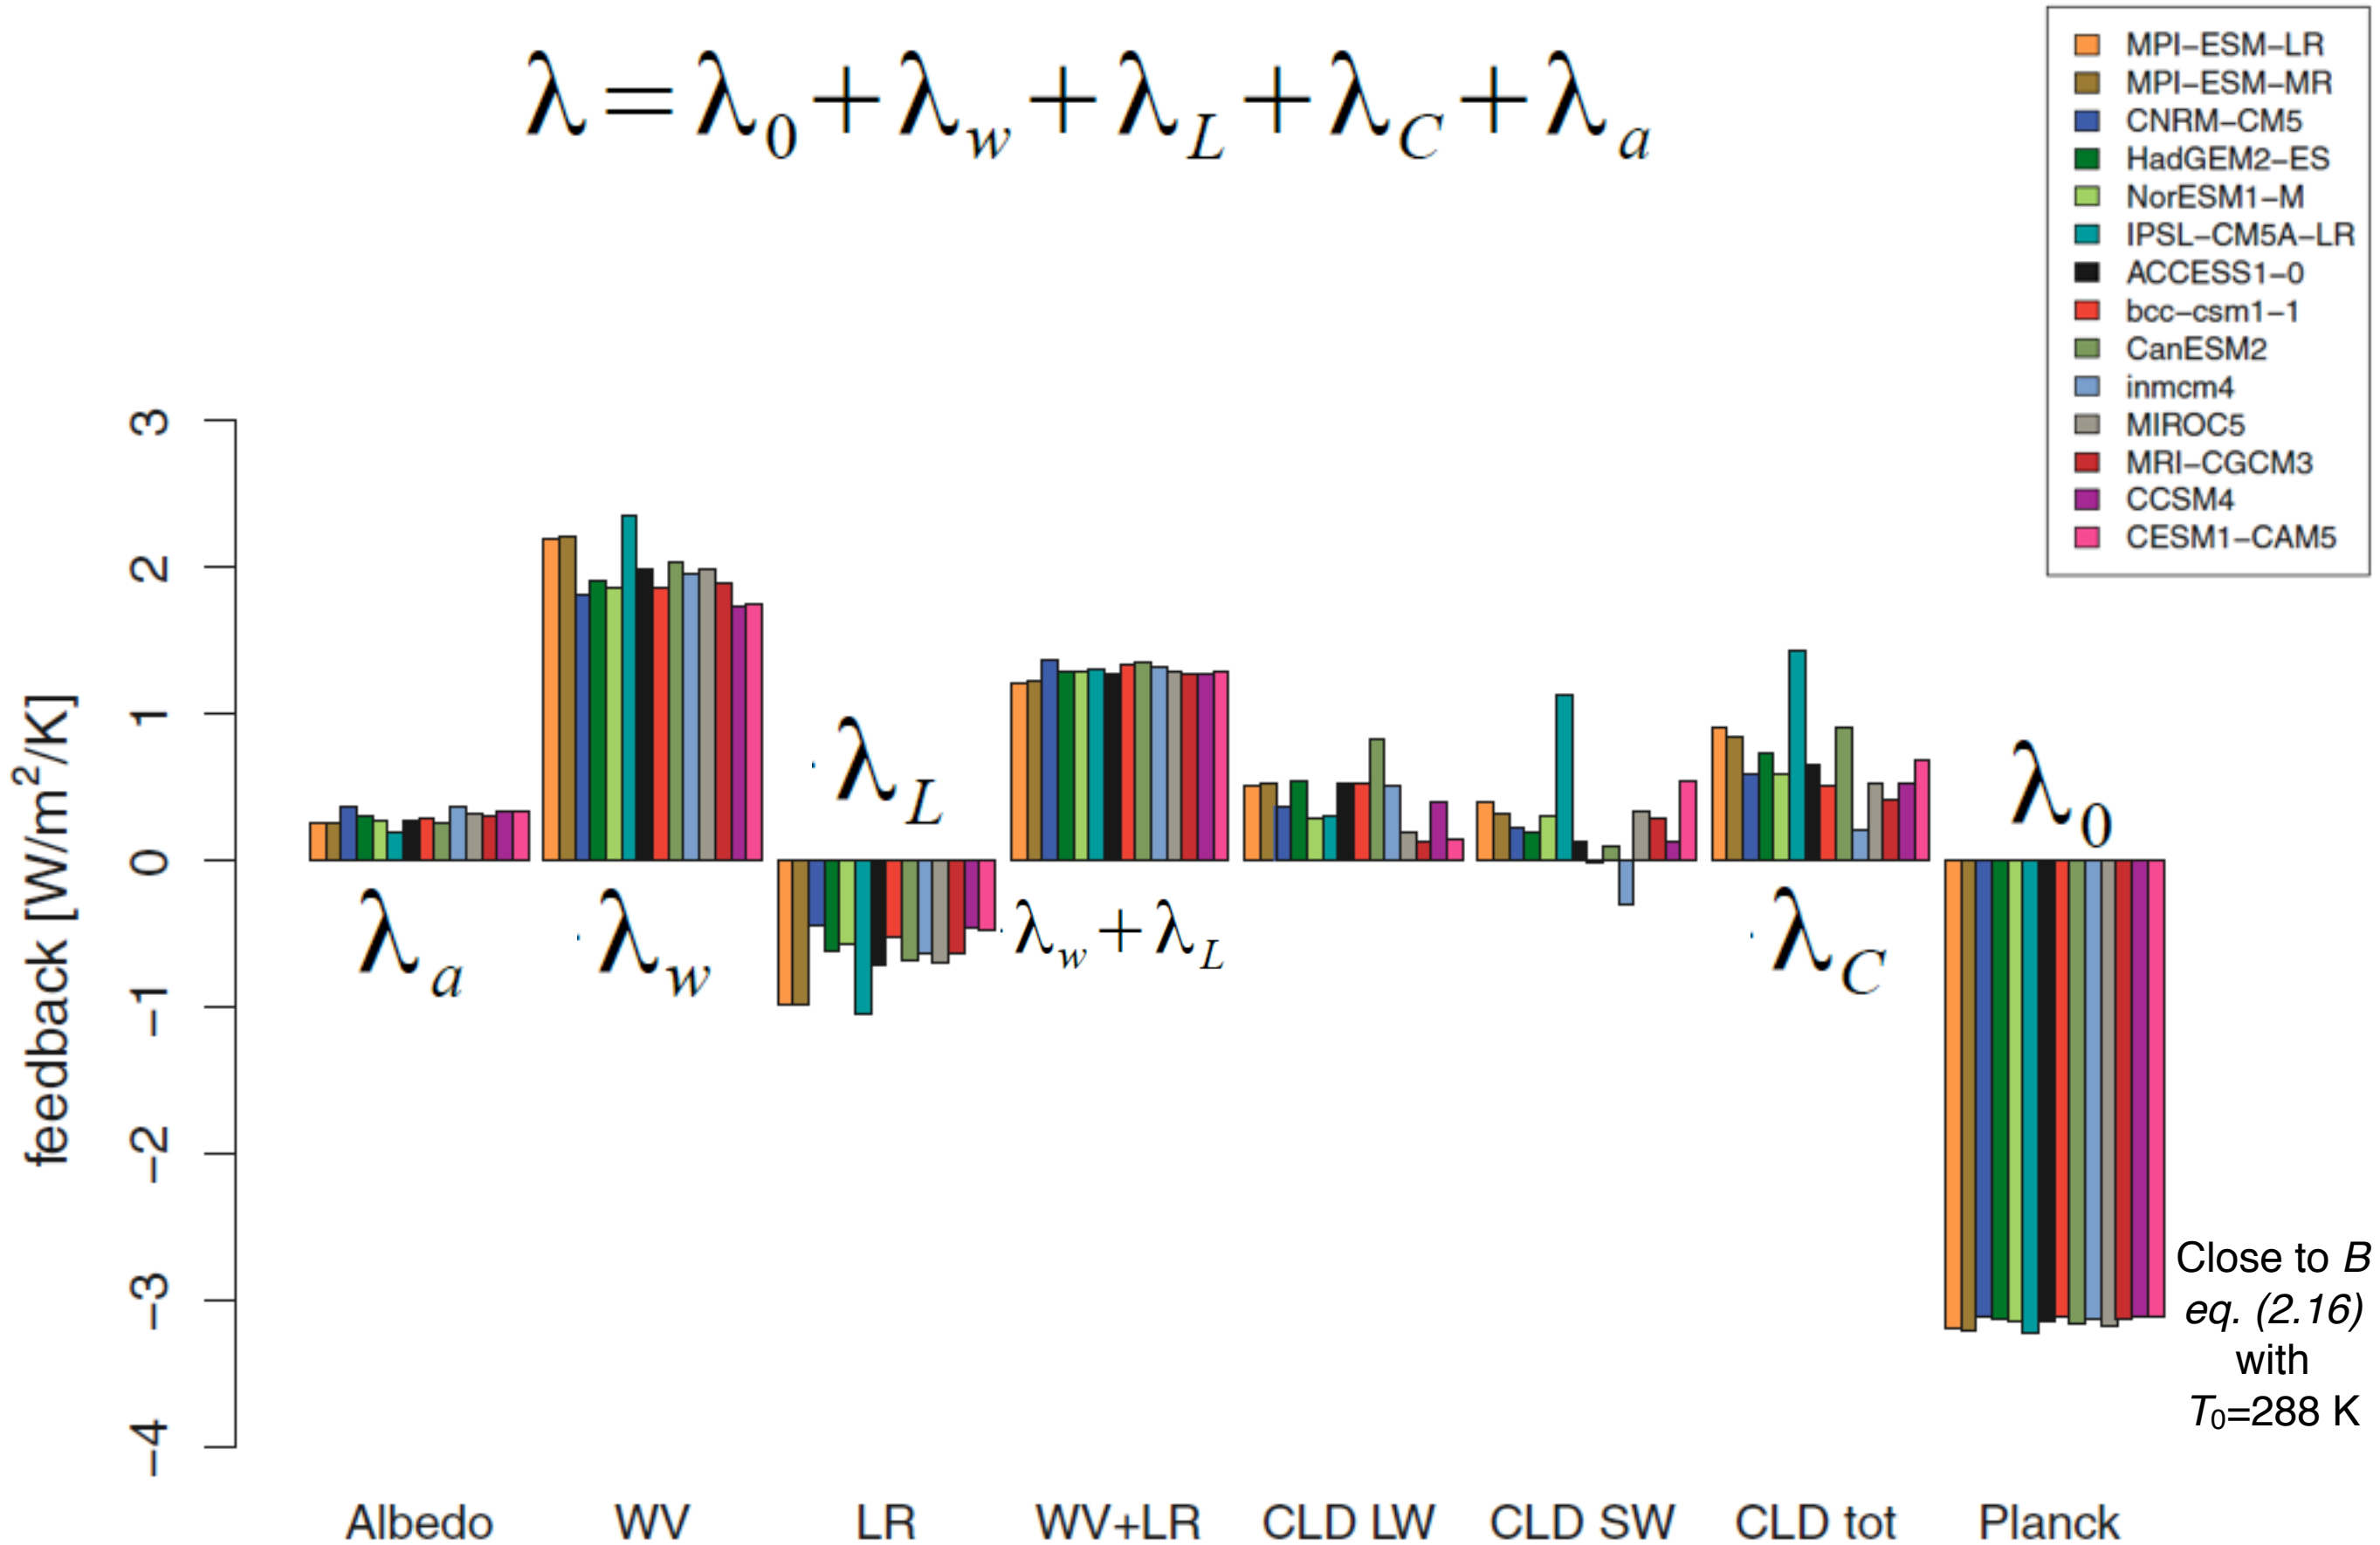

Feedback parameter

$$\lambda = \alpha^{-1} = \frac{\Delta Q}{\Delta T} = - \frac{\partial F}{\partial T} - \sum_n \left(\frac{\partial F}{\partial y_n} \frac{\partial y_n}{\partial T} \right) := \lambda_0 + \sum_n \lambda_n \quad (2.17)$$

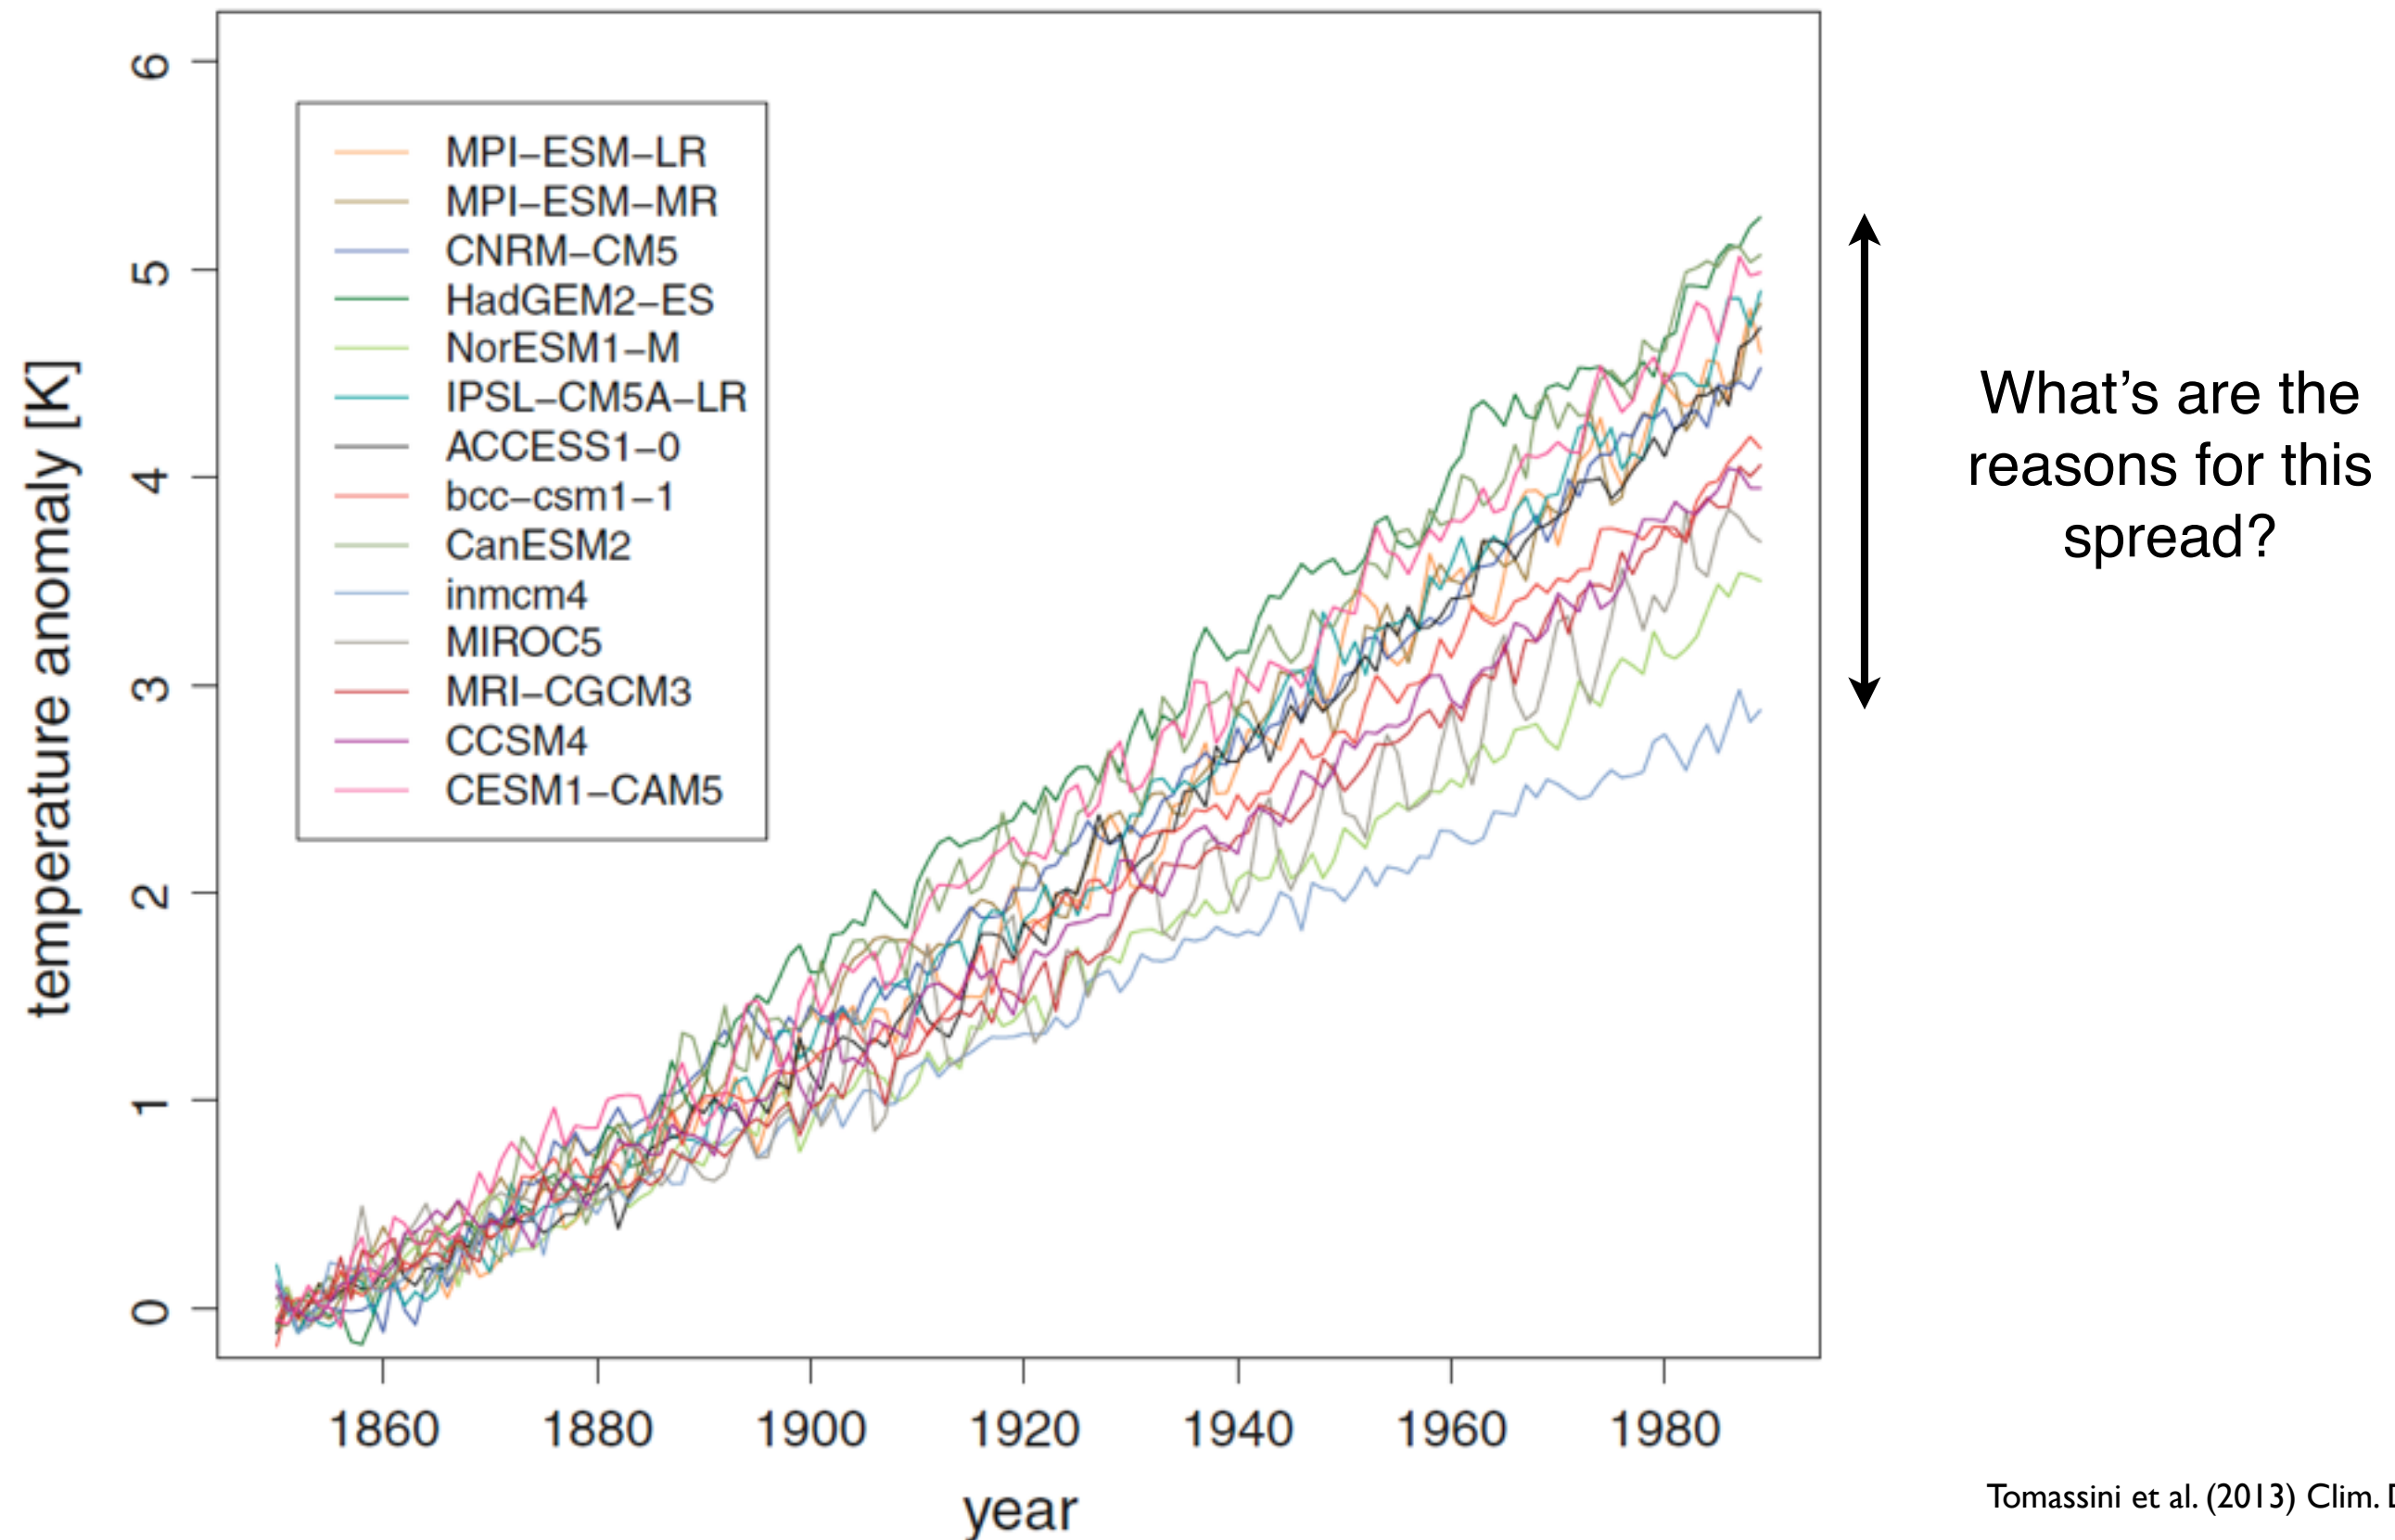

$$\lambda = \lambda_0 + \lambda_w + \lambda_L + \lambda_C + \lambda_a$$

Planck	water vapor	lapse rate	cloud	sfc albedo
--------	----------------	---------------	-------	---------------

$$\lambda = \lambda_0 + \lambda_w + \lambda_L + \lambda_C + \lambda_a$$

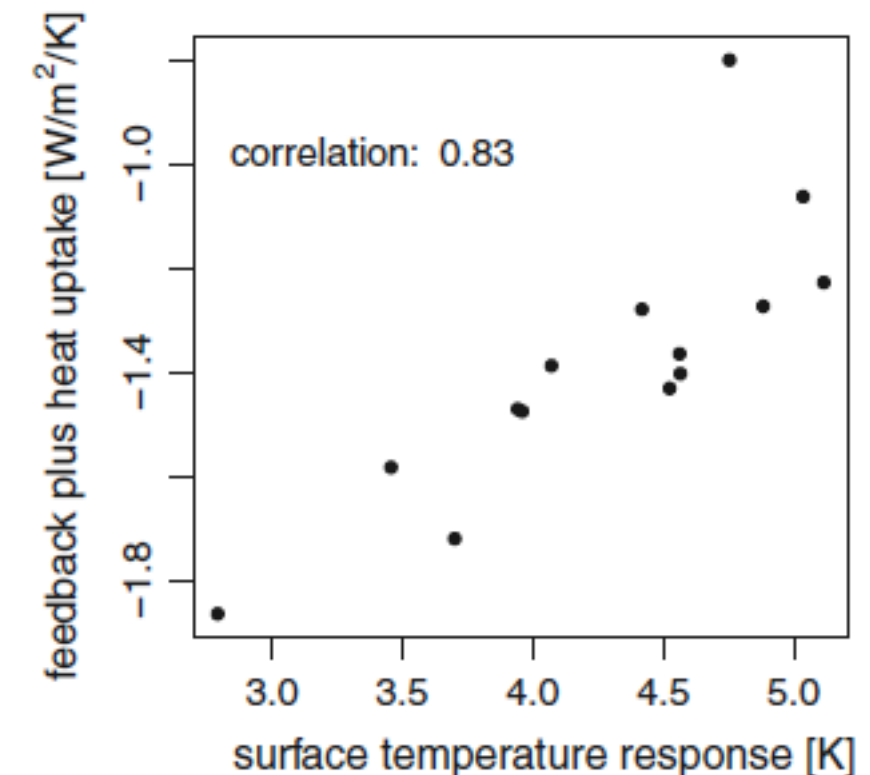

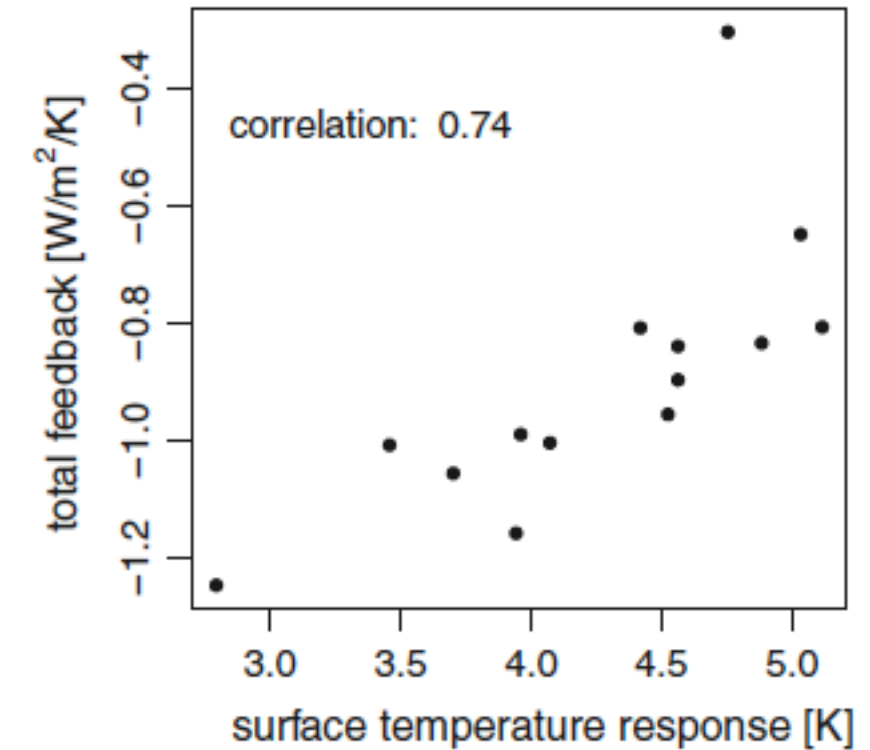

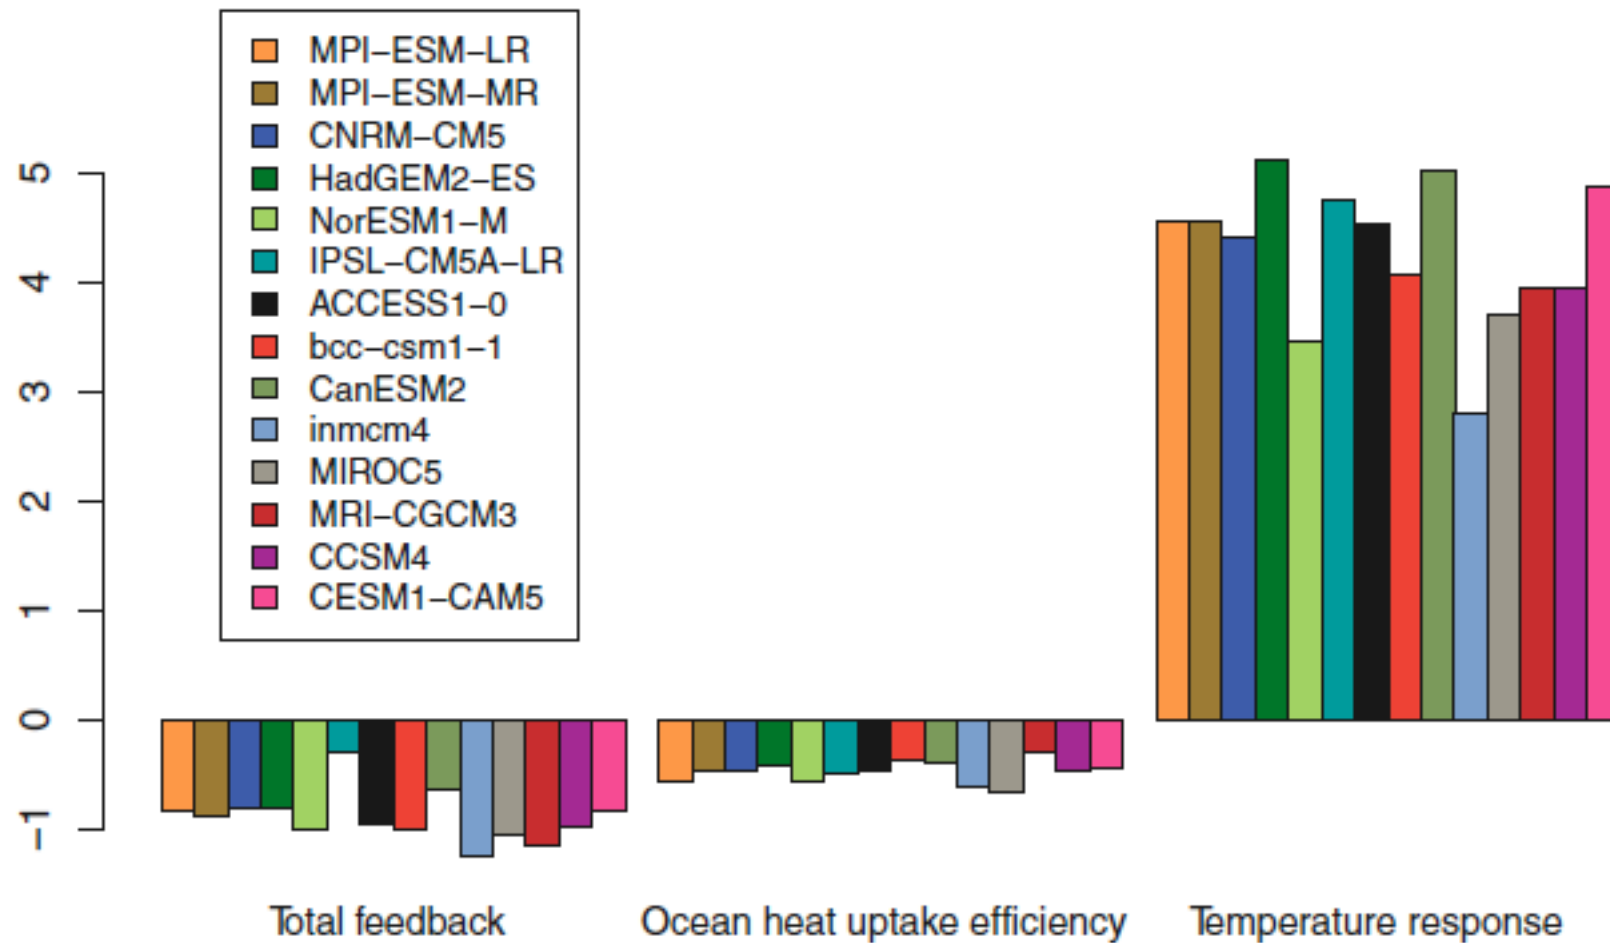

Transient response of CMIP5 surface temperatures to exponential CO₂ increase at 1%/yr

Two reasons have been identified:

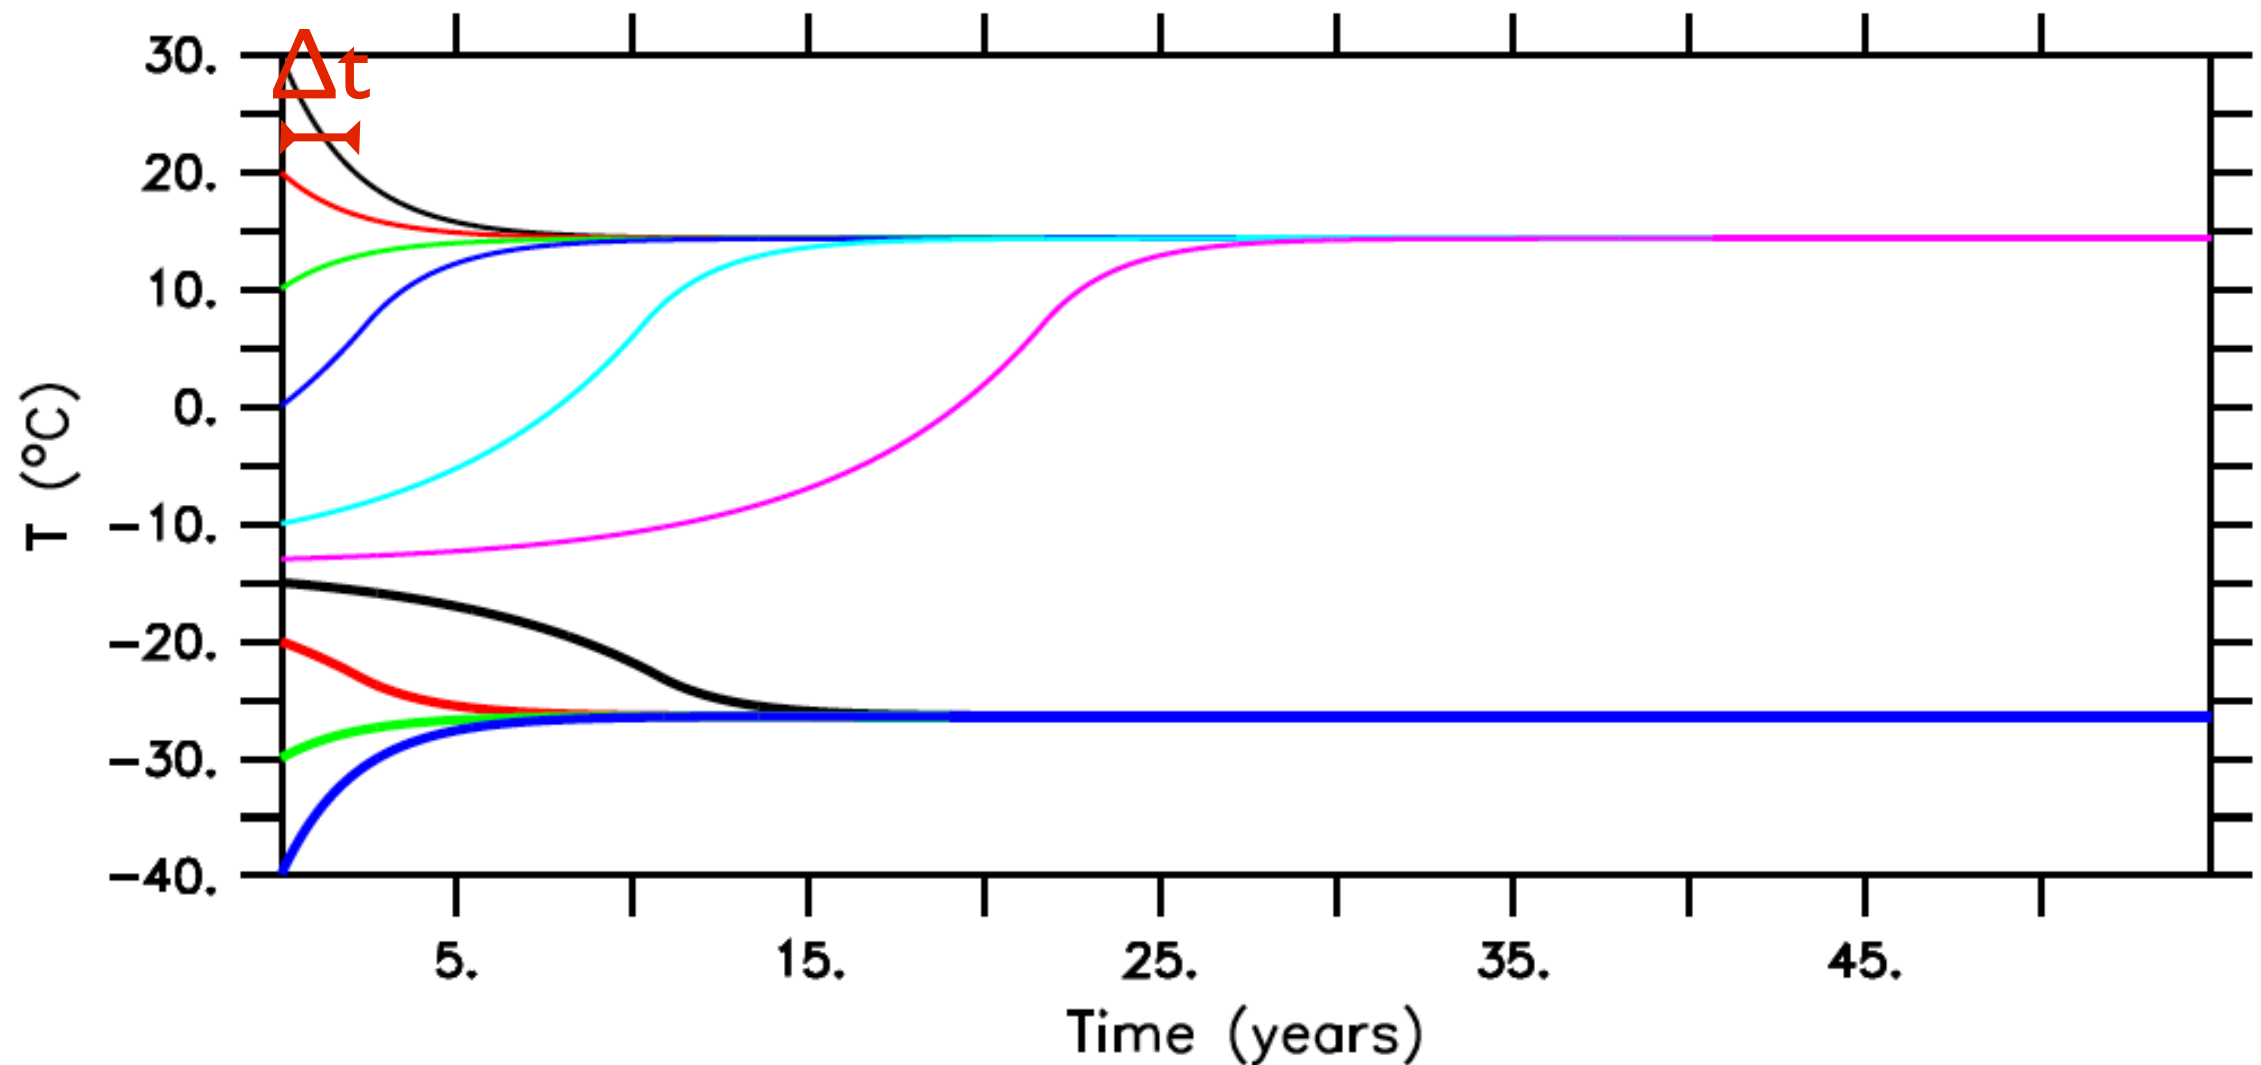

1. climate sensitivity (feedbacks)
2. ocean heat uptake

Stochastic Climate Models

0D-EBM Solutions

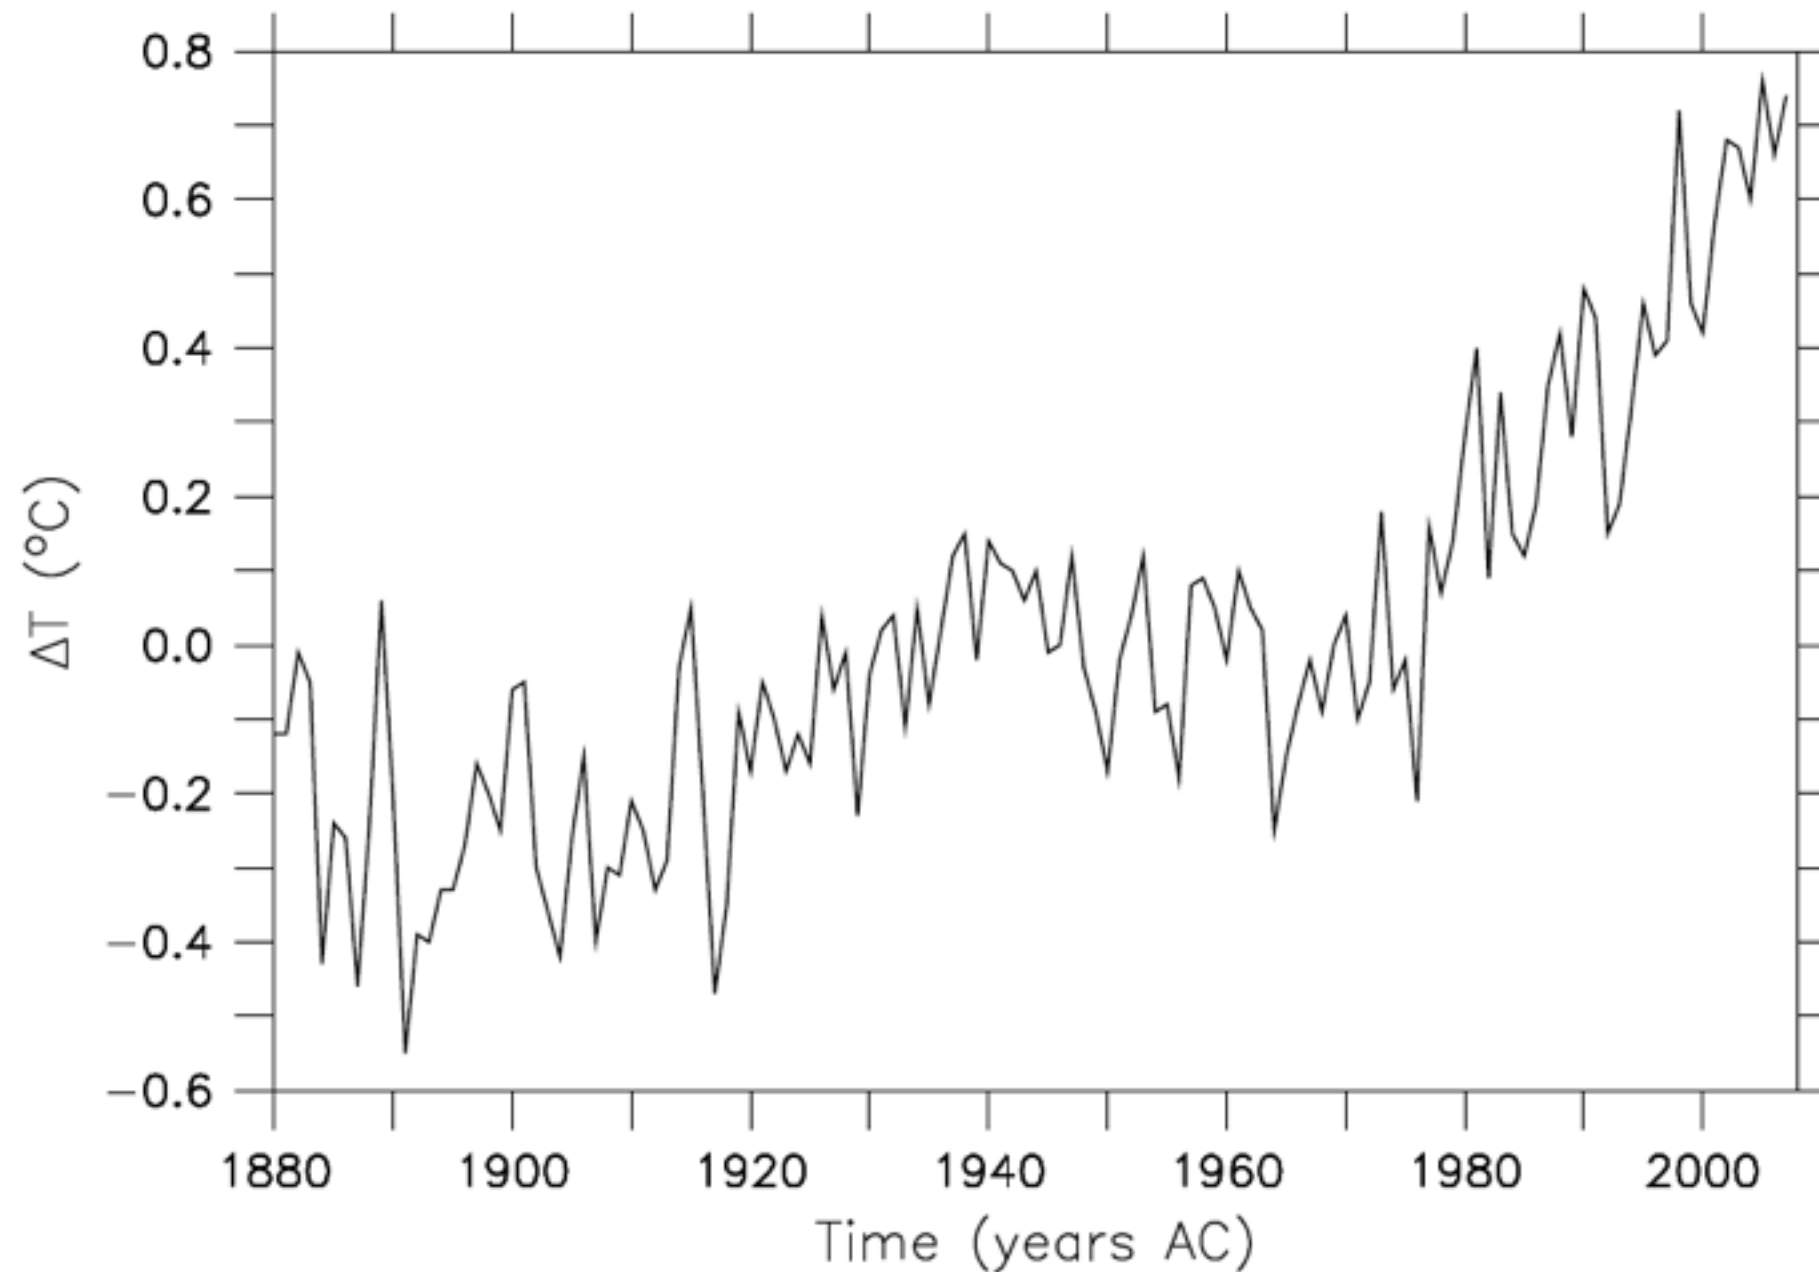

are smooth

Response timescale $\Delta t = C/B = 2$ years

real world has variability

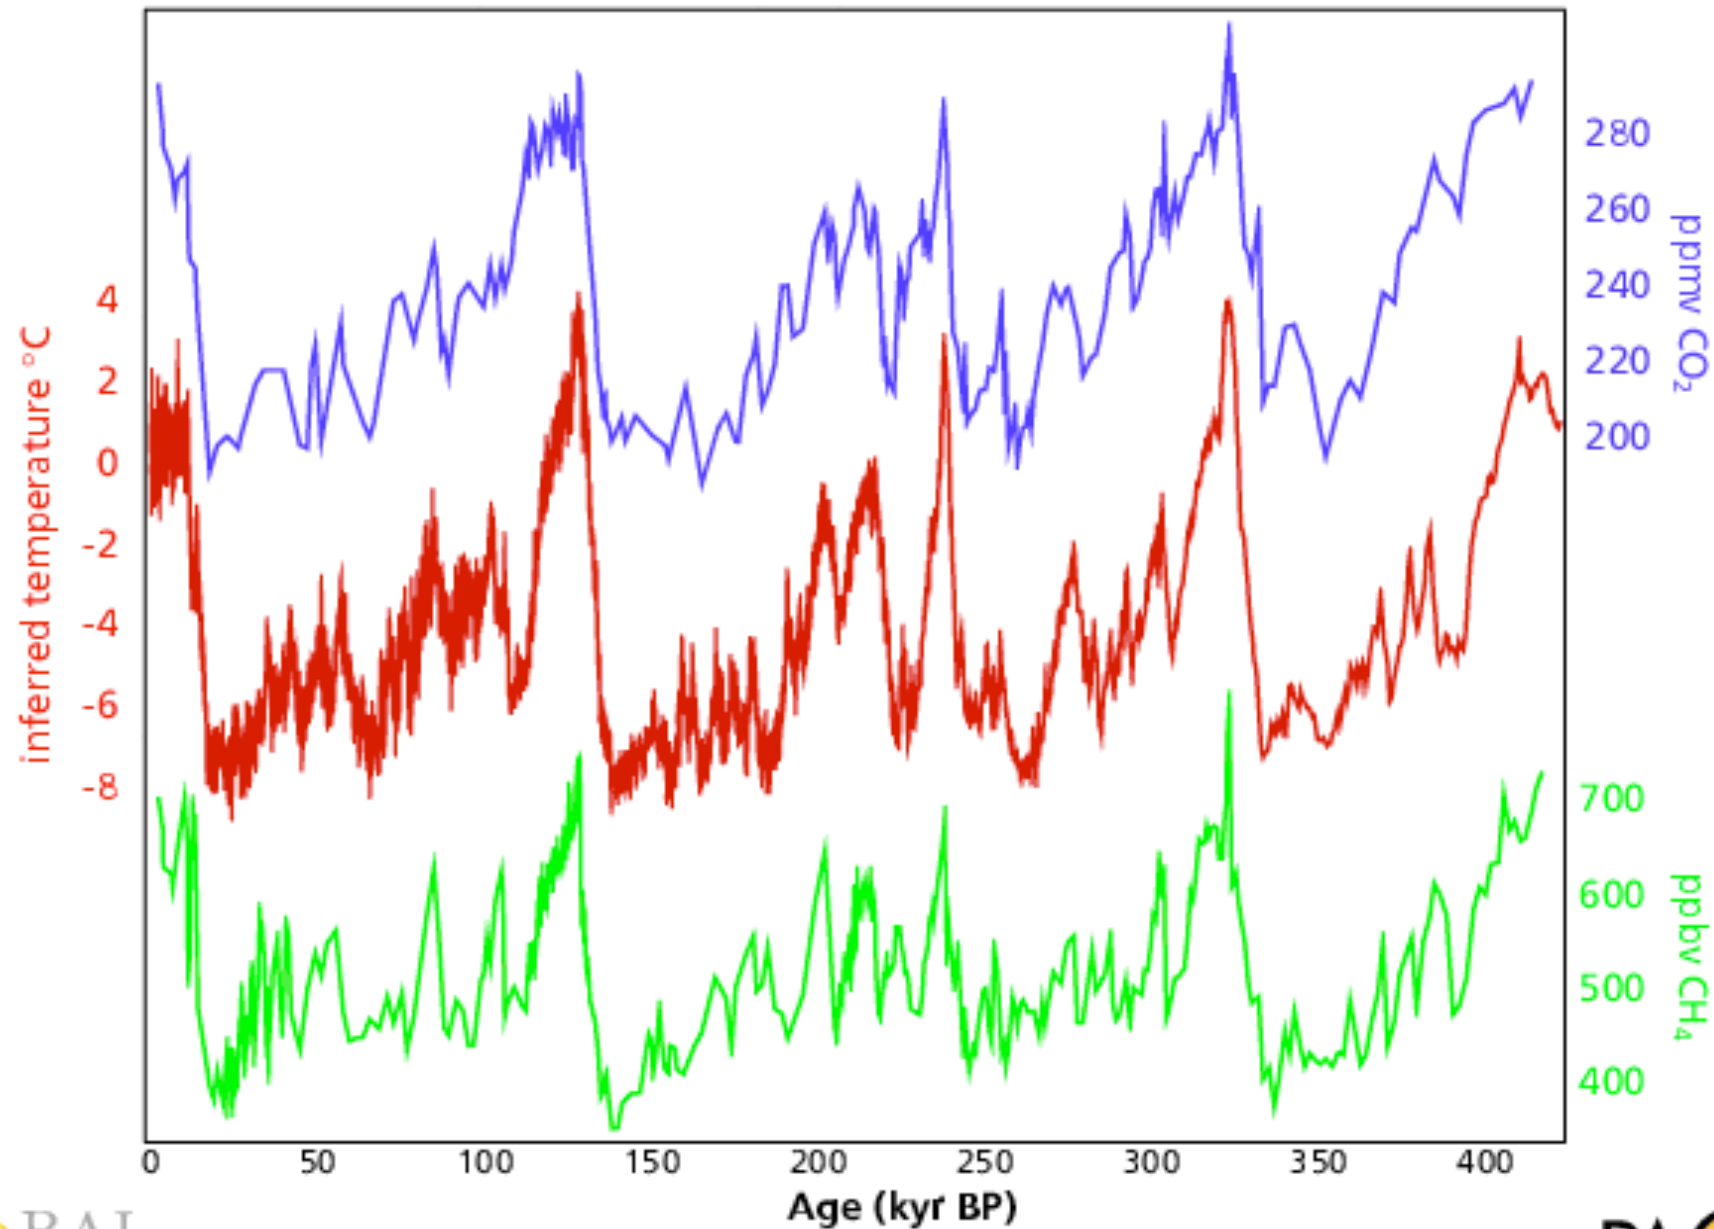

Variability last 150 years (instrumental period)

Global surface air temperature anomaly from NASA/GISS

Variability last 400,000 years (paleo)

4 glacial cycles recorded in the Vostok ice core

PAST GLOBAL CHANGES

6.1

Note that here as in many paleoclimate plots time moves to the left. This is because usually paleoclimate scientists plot measured variables versus depth in core (e.g. in sediment or ice core.)

Estimated spectrum of surface temperatures including paleoclimate proxies. From Huybers & Curry (2006, Nature 441, 329).

Anastasiya will lead discussion on Friday
